## EXECUTIVE SUMMARY

This report concerns the treatment and reuse of wastewater at fixed Army installations. The objective was to provide a tool that could be used by the Army in assessing the potential for water reuse at all their fixed facilities; in isolating those posts with the best reuse potential; and in evaluating conceptual reuse schemes at those posts.

To achieve this objective, two paths were pursued. First, major Army activities involving water and wastewater were identified and described as to: water use and wastewater characteristics, tolerable water quality if reclaimed water were to be used, potential as a donor or recipient of reclaimed water, and the potential for internal reuse at the activity. These data are essential and form a basis for constructing feasible reuse networks.

Secondly, a water reuse evaluation model was developed. This model involves three phases or tiers. Tier I is a comprehensive questionnaire that allows a concise overall evaluation of the reuse potential of a post in a short amount of time. Posts that score well on Tier I may then be evaluated under Tier II. This tier leads the evaluator through a deeper analysis of reuse possibilities on the post, and ends with a brief economic analysis of the fundamental reuse schemes selected for the post. Should this analysis show reuse to be economically beneficial, Tier III is applied. Tier III is a detailed survey that should be used only at posts with proven reuse potential. Field data from activity records and sampling, as well as conceptual reuse networks, are used as input to a mathematical model that determines piping, pumping, storage, and treatment requirements, and costs for the entire reuse system. At this point, the Army post should be ready for full-scale engineering design of the most effective reuse system.

## ACKNOWLEDGEMENTS

This User Manual was originally developed by SCS Engineers under USAF Contract No. F 29601-75-C-0019, for the Air Force Special Weapons Center (PMRC), Kirtland Air Force Base, New Mexico.

This User Manual has been slightly modified from the present contract with the Army Medical Research & Development Command, Ft. Detrick, Maryland.

## SECTION I

### INTRODUCTION

The cascade water reuse computer program has been developed to aid base engineers in designing wastewater reuse systems. The program requires various input data and human decision-making to be effective. The purpose of this manual is to explain in a comprehensive manner:

- . How the program works
- . What quantitative input data is required
- . Specifically how the data must be prepared for input
- . What output can be anticipated
- . What decisions will have to be made by base personnel

## SECTION II

### THE COMPUTER PROGRAM IN GENERAL

The program is divided into two separate phases. Phase I (Activity Description) assimilates activity data supplied by the base and prints out several forms for each activity showing flow patterns, effluent quality characteristics after various levels of treatment, the effects of recommended pretreatment units, and cascade potential. Output from Phase I is intended to assist the base engineer in selecting feasible activity cascade networks.

Phase II (Network Feasibility) evaluates the networks selected by base personnel. Output provides a comprehensive network description including the requirements for piping, pumping, storage, and treatment facilities, and finally the total cost of the entire cascade system. Continued modification of the most cost effective cascade networks should lead to an optimum reuse system for the base.

Note that the program can be used to simulate hourly flows throughout a day, or monthly flows throughout a year. The latter is important for bases with large seasonal fluctuations in water use.

### SECTION III

#### THE COMPUTER PROGRAM IN DETAIL

The following sections delineate in complete detail the required input and generated output data for both phases of the cascade program.

##### Phase I - Activity Description

For all parts of the program, input goes through two stages. Firstly, base personnel complete standard engineering data forms. Secondly, the data is transferred to computer forms from which the data deck can be punched directly.

##### Base Input

##### Preparation of Standard Engineering Data Forms

The first task in using the cascade reuse program is to gather all required base data. Forms 0 through XIII, described below and shown on the following pages, are provided for this purpose. Once completed, these forms provide all the information necessary to the program.

Note that there are duplicates for some forms. Select the form that corresponds to the daily or yearly program, whichever is being used.

FORM I      -      Activity Water/Wastewater Summary

Form I summarizes activity water and wastewater quality data: existing source water quality, tolerable source water quality, and existing final effluent concentrations. Typical concentrations for tolerable source water and effluent discharge are provided in Section II of the main report. These values can be substituted for actual base data if the latter is non-existent. However, it is important to note that the success of the entire program depends on the accuracy of the data. If the tolerable value of a constituent is not significant for that activity, a minus one (-1) can be entered for that concentration. This states in essence that any concentration is tolerable.

The sample Form I provided shows a water/wastewater summary for photographic processing. In this case, base data for tolerable source water quality was not available so the "typical" values provided on the form were used. Both source water quality, which is quite high, and a moderate final waste discharge with a BOD of 200 mg/l are shown. Base data was available for final effluent quality for all constituents so it was not necessary to use "typical" values.

FORM II - Activity Water Demand and Wastewater Generation

Form II summarizes activity water demand and wastewater generation flow information on an hourly basis for a typical day. If flow information is not available for all hours of the day, at least one hourly flow should be entered. Be sure to enter zero (0) for hours of inactivity. The program will interpolate whatever hourly data are provided to obtain flows for all hours.

Alternatively, if the yearly program is being used, then water demand and wastewater generation flow information for each month of the year must be provided on the yearly form. Note that flow units are in 1,000-gal per month for the yearly program, and gallons per day for the daily program.

The sample Form II provided shows daily water demand and wastewater generation data for an aircraft wash rack. As shown, there is zero flow until 8:00 a.m. when washing commences. Also there is some water loss in the washing operation, as seen by comparing the "water in" and "water out" columns.

FORM III - Source Water Quality/Cost

Form III is provided to summarize source water quality for each major water source on the base. In addition, the cost of procuring and/or treating these source waters is addended. Two sources are shown in the sample with separate qualities and costs. Sources are designated by both a number and a name of not more than five letters.

SAMPLE

FORM III

SOURCE WATER QUALITY/COST

Constituent	Concentration (mg/l)				
	Sources				
	Name				
	(No.)				
	(1)	(2)	(3)	(4)	(5)
	Wells	Lake			
BOD	0.1	0			
COD	0.3	0.2			
SS	0.1	0			
PHNL	0.01	0.01			
TDS	300	600			
NO <sub>3</sub>	5	15			
Cost: ¢/1000 gal	50	35			

FORM IV    Effluent Discharge Requirements/Cost

Form IV is to be used for delineating required final discharge concentrations for each major point of discharge from the base. Costs assessed to this discharge (excluding treatment), such as sewer surcharges, are also to be shown. The sample form shows two discharges, one to a river, one to the city sewer system.

Minue ones (-1) indicate infinity, or in essence, that no limit is required. Note also the difference in costs for discharge; the river discharge being free of charge while the flow going to the city is surcharged at a 30¢/1,000 gal average. Discharges are designated by both a number and a name of not more than five letters.

SAMPLE  
FORM IV  
FINAL EFFLUENT DISCHARGE REQUIREMENTS/COST

Constituent	Concentration (mg/l)				
	Discharges				
	Name (No.)

PHNL	1.0	-1			
TDS	-1	-1			
NO <sub>3</sub>	30	-1			
Cost: c/1000 gal	0	30			

FORM V      Special Treatment Removal Percentages

Form V summarizes removals achieved by the special pretreatment modules. Each constituent must be assigned a removal percentage, even if it is zero. Special treatments are designated by both a number and a code name of 10 letter maximum length. The sample form designates four special treatments: metal removal, oil and grease removal, softening, and chemical coagulation. The engineer is free to choose his own pretreatment units and removal efficiencies. He may also use those four provided in the sample form.

SAMPLE  
FORM V

SPECIAL TREATMENT REMOVAL PERCENTAGES

FORM VI - Regular Treatment Removal Percentages

Form VI provides the same information as Form V for the regular treatment chains. Note that removals are for the entire chain, not specific units within the chain. Again, base personnel are free to choose their own chains and removal efficiencies or they can use those provided in the sample form.

## SAMPLE

## FORM VI

## REGULAR TREATMENT REMOVAL PERCENTAGES

FORM VII      Special Treatment Chain Threshold Concentrations

Form VII provides data utilized in Phase I of the program only. For each special treatment, threshold concentrations for all constituents must be provided. In each case, an activity will be assigned the appropriate pretreatment if any of its raw wastewater concentrations are higher than one of the threshold concentrations. For example, assume an oil and grease threshold of 500 mg/l is assigned for the oil-and-grease-removal treatment module. Then for any activity generating a waste in excess of 500 mg/l oil and grease, the computer will not only provide the typical Phase I summary for that activity but will also provide a similar summary assuming grease and oil pretreatment at the activity. In this way, base personnel can review the Phase I output to determine the benefits of activity pretreatment. Note that for constituents that are not applicable to certain pretreatments, i.e., TDS in grease and oil removal, a minus one should be entered, which basically sets the threshold concentrations at infinity. Base personnel are free to use the values provided on the sample form or ones of their own choosing.

## SAMPLE

## FORM VII

Fe	100	-1	-1	-1			

FORM VIII      Cost Data/Piping Data

Form VIII provides necessary cost factors and indices as well as data on piping. The form is self-explanatory. Values shown in the sample form were those used by SCS Engineers during program testing. Naturally, the cost indices will change with time.

SAMPLE  
FORM VIII  
COST DATA

- . Rate of interest: 10 %
- . Current Engineering News Record Construction Cost  
Index: 2,103
- . Current Engineering News Record Labor Cost  
Index: 4.71
- . Estimated Equipment Life: 25 years

PIPING DATA

- . Maximum flow velocity in pressure pipes:  
5 ft/sec
- . Maximum flow velocity in gravity flow pipes:  
5 ft/sec
- . Number of possible pipe sizes: 12
- . List of pipe sizes: 1, 2, 3, 4, 6, 8, 10, 12, 15,  
18, 24, 36

FORM IX      Special Treatment Chain Costs

Form IX summarizes the cost coefficients used to cost special treatments. Capital and O & M cost coefficients are taken from the cost equations delineated in the main report. These equations are all of the form:

$$S = (A + BQ^c) \frac{I}{I_1}$$

Where:

- A = fixed cost (\$)
- B = unit cost (\$/gpd)
- c = scale factor
- Q = flow (gpd)
- I = current Engineering News Record cost index
- I<sub>1</sub> = January 1975 Engineering News Record cost index

It is imperative that all cost coefficients used as input data be represented as January 1975 dollars. The program will automatically update all costs for years following 1975 according to the current indices previously supplied.

Again, base personnel are free to use the coefficients provided on the sample form, or to generate their own cost curves and equations. Care must be taken to represent equations in the standard  $A + BQ^c$  form and to update to 1975 dollars.

It is important to note that the coefficients for each component of a multi-unit treatment chain (i.e., metal removal followed by chemical coagulation) must be listed separately.

SAMPLE

FORM IX

SPECIAL TREATMENT CHAIN COSTS

Treatment Chain Name	No. of Components* in Chain	Cost Coefficients					
		Capital			O&M		
		A	B	C	A	B	C
Metal Removal	1	0	435	0.41	16.24	57.93	0.41
Oil & Grease	1	0	36.28	0.71	0	0.31	0.82
Softening	1	5,000	0.02	1.0	0	0.36	1.0
Chem. Coag.	1	0	435	0.41	16.24	57.93	0.41

\* Be sure to include cost coefficients for each element of the treatment chain. For example, if two pretreatment units are combined in one chain, each must have its cost coefficient listed.

\* All cost coefficients must be represented in January 1975 \$.

FORM X      Regular Treatment Chain Costs

Form X provides the same data as Form IX for all regular treatment chains. Note that component coefficients are listed separately, i.e., the carbon adsorption chain shows coefficients for secondary, filtration, and carbon adsorption.

SAMPLE

FORM X

REGULAR TREATMENT CHAIN COSTS

Treatment Chain Name	No. of Components* in Chain	Cost Coefficients				
		Capital			O&M	
		A	B	C	A	B C
Primary	1	0	36.28	0.71	0	0.31 0.82
Secondary	1	0	1,159	0.51	0	362.9 0.40
Filtration	2	0	1,159	0.51	0	362.9 0.40
		0	29.97	0.63	0	5.95 0.63
Carbon Ads.	3	0	1,159	0.51	0	362.9 0.40
		0	29.97	0.63	0	5.95 0.63
		0	128.1	0.63	0	2.73 0.72
Rev. Osmosis	4	0	1,159	0.51	0	362.9 0.40
		0	29.97	0.63	0	5.95 0.63
		0	128.1	0.63	0	2.73 0.72
		13,550	0.10	1.0	75.78	0.13 1.0

\* Be sure to include cost coefficients for each element of the treatment chains. For example, if three units are combined in one chain (i.e., secondary, filtration, and carbon adsorption), each must have its cost coefficient listed.

\* All cost coefficients must be represented in January 1975 \$.

FORM XI      Cascade Network Diagram

Form XI is provided for each cascade network diagram. As described in Section IV of the main report, "Program Synopsis," this diagram must include all activities, BTS's, specified activity pretreatments (optional), specified treatment at BTS's (optional), all BTS make-up and discharge lines, and also the lengths of all piping. To eliminate the costs for existing piping, assign all existing pipes a zero length. A sample network is provided.

FORM 11

FORM XII    Activity Pretreatment

Form XII delineates all activity pretreatments specified by base personnel. For all networks, each activity must be designated either a zero (meaning no pretreatment) or the number of the pretreatment desired. As shown in the sample, the aircraft wash rack (A/AWR) has been assigned chemical coagulation pretreatment, and the photo shop metal-removal pretreatment for some of the networks.

SAMPLE  
FORM XII

ACTIVITY PRETREATMENT

Activities	Pretreatment No.									
	Network No.									
	1	2	3	4	5	6	7	8	9	10

4. OFF	0	0	0	0	0	0	0	0	0	0
5. PHOTO	0	1	1	0	1	1	1	1	0	0
(etc.)										

FORM XIII      Specified Regular Treatment at BTS's

Form XIII is provided so that base personnel may fully delineate any treatment they desire at a BTS. Three options exist in regards to treatment at a BTS:

1. The engineer specifies nothing and allows the program to compute required constituent removal percentages and select the appropriate treatment chain.
2. The engineer specifies a treatment chain. The program then proceeds to compare the removals provided by that chain with those required. If the specified chain can produce a satisfactory effluent in all constituent categories, then that chain is used. If, however, one or more of the contaminants are not satisfactorily removed, the program will assign a more advanced treatment chain to that BTS.
3. The engineer specifies removal percentages for each constituent. Again, the program will compare specified and required removals, select the larger in each case, and choose the appropriate treatment to meet those removals. As shown in the sample form, space is provided for specifying individual constituent removals or whole treatment chain at a BTS.

SAMPLE

FORM XIII

SPECIFIED REGULAR TREATMENT AT BTS'S

Network No.	BTS No.	Specified Removal Percentages							Specified Regular Treatment Chain No.
		Constituents							
		BOD	COD	SS	etc				
2	3								3

FORM XIV - BTS Make-Up Water Treatment

Each BTS in a network requires a make-up water line in the event that additional water is needed to meet demand. The option exists of having this make-up water blended and treated with the rest of the influent to the BTS or of having the make-up by-pass treatment and be blended directly with the treated BTS effluent. In most cases, high quality make-up (usually the potable supply) will be used, in which case blending should occur after treatment. However, if poor quality water, from another BTS for example, is used as make-up, it may be advantageous to have it treated at the BTS it is supplying. The sample form shows instances of the latter circumstance. Note that each BTS must be accounted for.

## FORM XIV

## BTS MAKE-UP WATER TREATMENT

Network No.	BTS No.	Make-Up Treatment (1)	Network No.	BTS No.	Make-Up Treatment (1)
1	1	F			
	2	F

	2	F			
	3	T			
4	1	F			
	2	F			
	3	F			
	4	F			
	5	T			

T - Make-up treated at BTS after blending with influent.  
 F - Untreated make-up blended with BTS effluent.

### Preparation of Computer Forms

The following sections describe the translation of all data from the engineering forms to the computer forms that will be used to punch the data deck. In each case, sample pages are provided for illustration. It is highly unlikely that all lines and pages will be used. Unused lines and pages may be left blank.

Note that throughout the computer form deck, all numbers are right justified in the field and that all words or letter codes are left justified.

#### Phase I

##### Input

As previously discussed, Phase I input provides general base data, activity descriptions, source water qualities, discharge requirements, etc.

The following section describes in detail the transferring of this information from the engineering forms to the computer forms.

Remember to use the appropriate forms for the daily or yearly program, whichever is being used. Again, note that flows for the yearly program are expressed in units of 1,000-gal per month.

# PHASE I

## DATA PRESENTATION

<u>Page</u>	<u>Line</u>	<u>Description</u>
1	1	T in 1st col. if Phase I printout is desired; F if it is not.
		T in 2nd col. if network flow and concentration printout is desired; F if it is not.
		T in 3rd col. if cost summary printout is desired; F if it is not. Be sure to exclude cost data from data deck if F is specified here.
1	2	The name of the base, including blank spaces, in cols. 1-25 (Form 0).
1	3	The total number of constituents (contaminants) to be monitored in the 1st 12 cols. The maximum number of contaminants is 30 (Form 0).
	4, 5	The names of all the constituents in 5 col. blocks (Form 0)

# PHASE I

## DATA PRESENTATION

<u>Page</u>	<u>Line</u>	<u>Description</u>
2	1	Total number of water sources in 1st 12 c's. Maximum number of sources is 5 (Form III).
2	2	Names of sources in 5 column blocks, starting with the 1st column (Form III).
2 3	3-10 1-15	Constituent concentrations (mg/l) for source water(s). Use as many lines as needed to complete concentration summary of source 1, 2, etc. Be sure to follow the same constituent order as listed on page 1. Place all numbers in 12 block c's (Form III).

### Output

Output from the Phase I Program fully describes the activities and possible cascade arcs.

The tables on the following pages are examples of the information provided.

Table 1 shows a summary of the hourly and cumulative flows into and out of each activity. In addition, graphs of these flows are provided. The aircraft wash rack shown here, used only 3,000 gal per day to wash one or two planes in the middle of the day. Some water was lost of evaporation and runoff as only 2,400 gal was discharged.

Table 2 provides a water-quality summary for each activity. The following information is shown:

- . Tolerable source water concentrations. The aircraft wash rack, for example, is estimated to be able to accept water with BOD and SS of 20 mg/l.
- . Actual concentrations into the activity.
- . Actual concentrations out of the activity.
- . Degradation through the activity in mg/l.
- . Quantity of contaminants into and out of the activity, and degradation in lbs/day.

Table 3 delineates activity wastewater concentrations after various levels of treatment; none, primary, secondary, and three tertiary systems are shown in the example. As can be seen, this wash rack discharged a very strong waste that had a significant COD concentration (337 mg/l) even after carbon adsorption tertiary treatment. The treatment chains shown in Table 3 are additive, i.e., the carbon adsorption heading represents carbon adsorption added on to filtration and secondary treatment.

Table 4 shows the same type of data as Table 3 except, in this case, the program has assigned chemical coagulation pretreatment to the aircraft wash rack wastewater which then proceeds through the other regular treatment chains. The effect of the pretreatment alone can be gauged by comparing the "none" columns (no regular treatment) on Tables 3 and 4.

Table 4  
ACTIVITY MAXIMUM CONCENTRATION AFTER TREATMENT  
( $\mu\text{g/L}$ )

[illegible]

As shown, chemical coagulation is specified as removing 50 percent of the BOD and COD and 70 percent of the suspended solids. The program assigns these pretreatments to activities whenever the raw discharge exceeds one of the pretreatment threshold concentrations designated by base personnel. Table 4 aids in determining the feasibility of activity pretreatment.

Table 5 summarizes the suitability of each activity effluent for reuse in other activities. The acceptability of each constituent for reuse after various levels of treatment is shown. This table aids the engineer in isolating troublesome contaminants and evaluating the effect of treatment on contaminant removal.

As shown in the example, under each treatment option, all base activity codes are listed vertically. An "X" means that the constituent is acceptable for reuse in the activity it falls under after going through the treatment designated. For example, looking at  $\text{NO}_3$ , it can be seen that the raw discharge from the aircraft wash rack is acceptable for reuse in all activities but the photo shop. Moving across the  $\text{NO}_3$  row, one notices that  $\text{NO}_3$  is sufficiently removed for use in photo processing only after the carbon adsorption chain. Similarly, COD is never acceptable for reuse regardless of treatment. An "X" for every constituent under one activity means that the entire effluent is acceptable for cascade to that activity.

For activities assigned pretreatment (i.e., chemical coagulation at the aircraft wash rack), a table similar to Table 5 is provided that assumes pretreatment is operative at the activity. This table allows engineers to easily evaluate the feasibility of pretreatment at an activity and its ability to enhance the quality of effluent for reuse. As shown in Table 6, the aircraft wash rack with chemical coagulation is now discharging acceptable water for reuse in several other activities after reverse osmosis (an unlikely event but one that shows the value of the table).

Table 7 is the key Phase I output table that condenses the output provided into one base summary table showing acceptable cascades between activities on the base. Activities are listed with pretreatment, if applicable. An "X" means that the effluent from the activity in that row is acceptable for cascade to the activity in the column, after the treatment designated.

A number "1" instead of an "X" indicates that only one constituent in the wastewater was not acceptable; a "2"

Table 6  
COMPARISON OF ACTIVITY EFFICIENT FOR REDUCED

[illegible]

means similarly that two constituents were over tolerable limits for cascade.

As shown in the sample table, the base housing effluent ("HOUSE") is acceptable for reuse after secondary treatment in all irrigational activities: general irrigation (GENIR), office area irrigation (OFFIR), golf course irrigation (GOLF), and Arnold Heights housing irrigation (AHIRR). The photo shop wastewater is acceptable for reuse as irrigation water after filtration tertiary treatment except for one constituent which proved to be cyanide.

This table should aid greatly in locating feasible cascades and pretreatments of most potential, as well as pinpointing cascades hindered by just one or two troublesome contaminants. Review of these individual activity summaries may show that the problem constituent can be eliminated or treated somehow to achieve an acceptable water for cascade.

These tables as output from Phase I should be valuable in helping base personnel construct feasible cascade reuse network diagrams.

## Phase II

### Base Input

Phase II input involves the representation of cascade networks to be analyzed and the specification of appropriate cost data.

Cost data that must be provided include the following:

- . Rate of interest (%)
- . ENR Construction Cost Index
- . ENR Labor Cost Index
- . Life of the system (yrs)
- . Costs of regular and special treatment units or chains
- . Costs of piping, pumping, and storage
- . Cost per 1,000 gal for water supply and discharge

With the aid of the Phase I output, base personnel should be able to develop feasible cascade networks. These networks have to be presented in proper format along with all lengths and possible sizes of pipe not already existing in the system.

The most difficult part of data representation is the cascade network itself. The first step for base personnel is to draw flow diagrams of possible networks similar to the one shown in Figure 1 on the following page.

As shown, the network includes two types of units: activities (base housing, vehicle wash rack, etc.), and BTS's (Blending-Treatment-Storage Units). The BTS's are the crux of the network and full understanding of their placement and function is absolutely necessary.

BTS's are to be placed between any two connected activities, between activities and sources, and between activities and discharges. They serve as focal points for computer calculations of flow, storage, concentrations, treatment, and costs. Each BTS has a make-up line and an overflow in discharge lines. Figure 2 shows a blown-up view of a BTS and its simplification into a one-square symbol. Addition of makeup water can occur before or after treatment as specified by the engineer. A complete description of the mathematics involved with blending, treatment, storage, overflow, and make-up are discussed in Appendix 3.

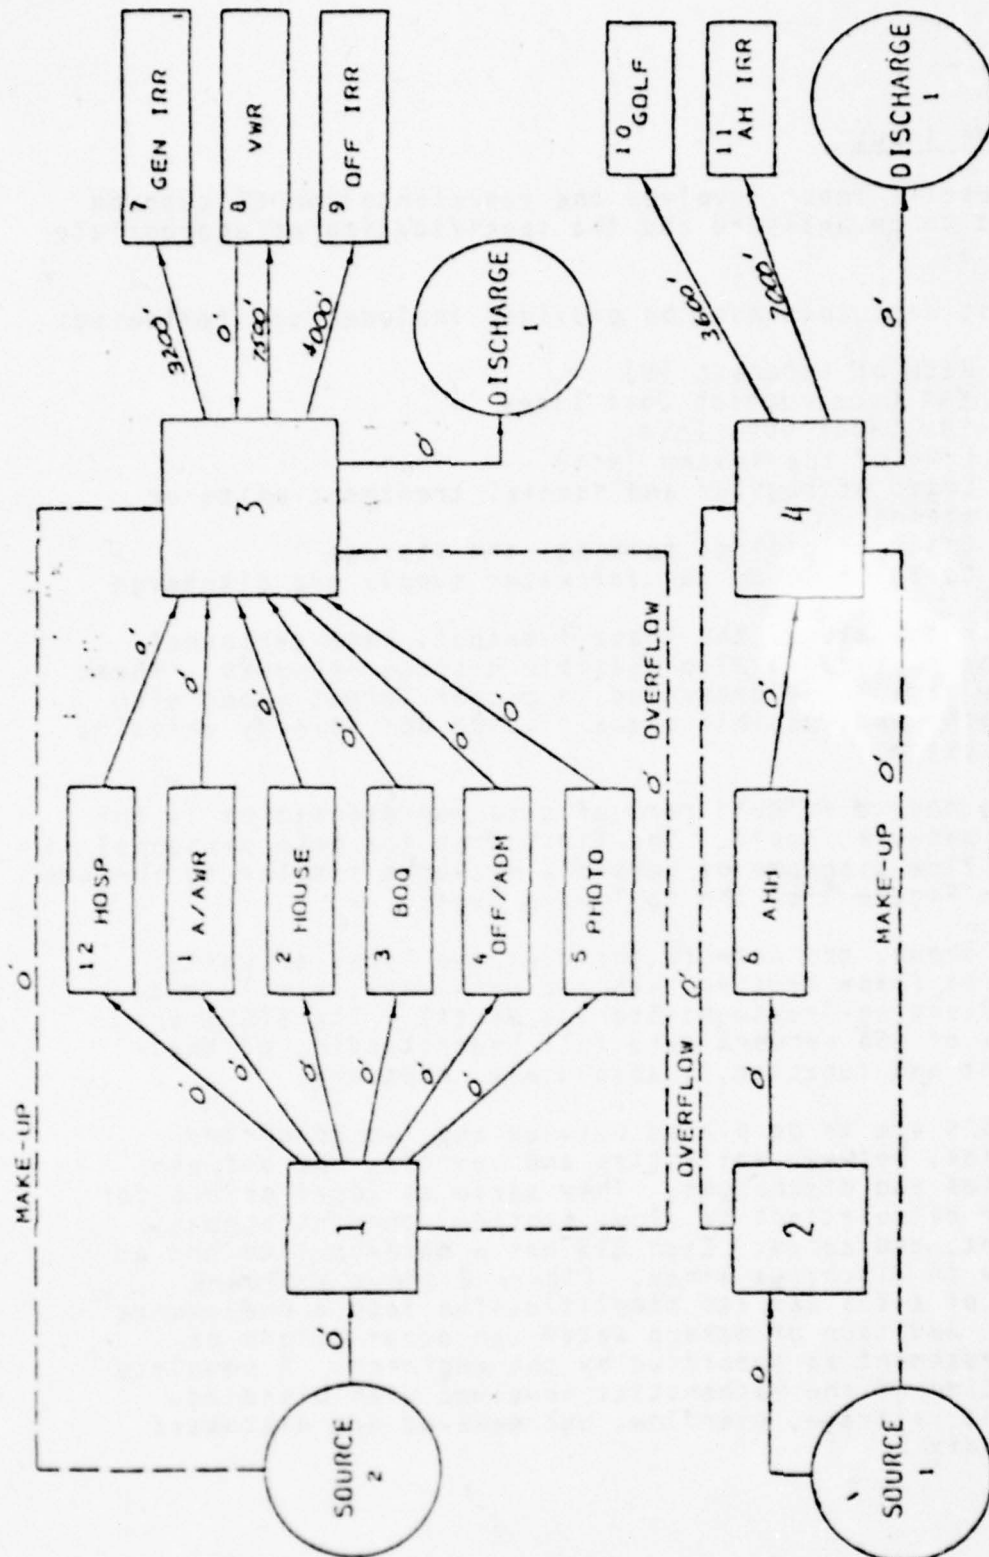

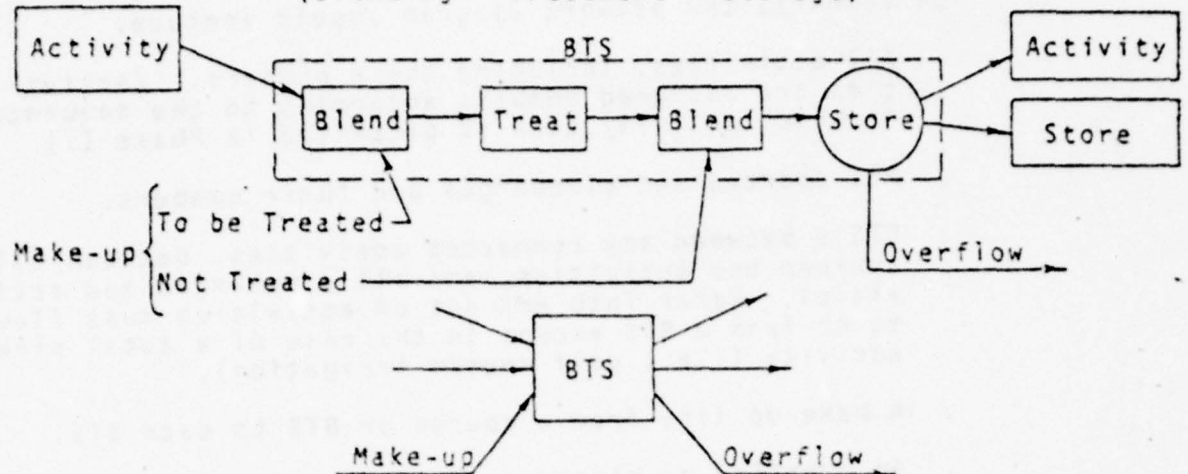

FIGURE 1  
MARCH AFB  
NETWORK NO. 1

FIGURE 2

## BTS UNIT

(Blending - Treatment - Storage)

The network displayed in Figure 1 includes a total of 12 activities:

<u>No.</u>	<u>Code</u>	<u>Name</u>
1	A/AWR	Aircraft/age wash rack
2	HOUSE	Main base housing
3	BOO	Bachelor officers' quarters
4	OFF	Office/administration
5	PHOTO	Photographic processing
6	AHH	Arnold Hts. housing
7	GENIR	General grounds irrigation
8	VWR	Vehicle wash rack
9	OFFIR	Office/adm. grounds irrigation
10	GOLF	Golf course irrigation
11	AHIRR	Arnold Hts. irrigation
12	HOSP	Hospital

Also shown are the four BTS's, each with a make-up line and overflow or discharge. In actuality, Source 1 is Colorado River water with BTS 2 being the existing water treatment plant. Source 2 is well water with BTS 1 just a fresh water storage facility. BTS's 3 and 4 are the two existing base sewage treatment plants. The main purpose of this network was to test the feasibility of total effluent reuse for irrigation.

Piping lengths have been shown for new pipes. All other lines are assumed to be existing or non-functional, and were assigned 0 length.

It is important that all piping be given a length, even if it is zero.

In summary, the network diagram should include:

- . All activities, including their numbers. (Activities are assigned numbers according to the sequence in which activity data is presented in Phase I.)
- . All sources and discharges and their numbers.
- . BTS's between any connected activities, between all sources and activities, and all discharges and activities. Water into and out of activities must flow to or from a BTS except in the case of a total sink activity (i.e., golf course irrigation).
- . A make-up line from a source or BTS to each BTS.
- . An overflow or discharge from each BTS. (Note: One occurrence must be avoided--closed loops comprised of source and discharge lines between BTS's. A check to avoid this occurrence is to reverse the flow direction of all source lines to BTS's on the network diagram and to look for any closed loops comprised of BTS discharge lines and the reverse flow BTS source lines. See Figure 3 for examples of permissible and non-permissible loops.)
- . All pipe lengths in the system. Zero length can be specified for existing lines.

Proper translation of this network to a tabular format readable by the machine is described and illustrated in the following sections. Specific instructions follow for filling out all Phase II input forms. In each case, sample forms are provided for illustration.

# PHASE II

## DATA PRESENTATION

### Description

### Line

### Page

Cost of water (\$/1000 gal) for each source, 1st 12 c block (Form III).

Cost of final discharge (\$/1000) gal for each final effluent, 1st 12 c block (Form IV).

Number of BTS's in network, 1st 12 c block. Maximum number of BTS's is 20 (Form XI).

Number of activities out of 1st BTS, c's 1-12. The number of source feeding BTS 1, c's 13-24. If another BTS is the source, then put that BTS number in preceded by a minus sign. The number of discharge taking water from BTS 1, c's 25-36. If another BTS is accepting the overflow or discharge, then put that BTS number in preceded by a minus sign (Form XI).

C's 37-48 are provided for specification of regular treatment at the BTS (Form XIII):

0 denotes no treatment specified by the user. Let program calculate necessary removals and facilities.

1, 2, up to 7 (number of regular treatment chain) denotes that user is specifying the removals provided by that treatment chain at BTS 1. Program will calculate required removals regardless, compare them to those specified, and select the larger for each constituent.

-1 denotes that user is specifying particular removal percentages at BTS 1. Again, program will calculate removals required, compare to those specified, select the larger for each constituent.

## PHASE II

### DATA PRESENTATION

<u>Page</u>	<u>Line</u>	<u>Description</u>
38	1	Column 60, place T if make-up water to BTS is to be treated at that BTS; F if make-up water is to by-pass treatment and to be blended with treated effluent from the BTS (Form XIV).
38	2	C's 1-12, number of 1st activity out of BTS 1 (numbers must coincide to activity number from initial activity list) (Form XI).
		C's 13-24 number of BTS accepting discharge from that activity. If activity is a total sink (i.e., golf course), then denote BTS out by a zero (Form XI).
		C's 25-72 continue same procedure for 2nd and 3rd activity out of BTS (Form XI).
38	3-6	Continue same procedure as line 2 for remaining activities out of BTS.
39	1-5	If regular treatment removals have been specified by user (-1 in c 48 of line 1), these percent removals are placed in 12 c blocks (Form XIII).
40-52	All	Repeat pages 38 and 39 for each BTS in the network. Note that if no treatment is specified, then page 28 is not necessary.

# LENGTH OF PIPE FOR OVERFLOW FROM BIS'S

## Output

For each network provided by the user, Phase II of the program produces a tabular network description and summarizes flows, concentrations, storage, and treatment at each BTS. All costs associated with the reuse system including water purchase and discharge fees are clearly delineated and ultimately summarized on an annual basis to yield a total yearly cost for reuse. A description of the Phase II printout follows.

The first page of output describes the network to be evaluated. Table 8, provided here, describes the sample cascade network previously shown in Figure 1. As can be seen, the network summary centers around a description of the flows into and out of each BTS unit. BTS 3, for example, shows the following:

- . Source water (if needed) is drawn from source No. 2 - Wells. This source water or make-up is not treated at the BTS but blended with the effluent as designated by the word "UNTREATED."
- . Overflow from BTS 3 (if needed) goes to discharge No. 1 - DISCH.
- . Activities discharging into BTS 3 are: No. 12 - hospital, No. 1 - aircraft washing, No. 2 - base housing, No. 3 - BOD, No. 4 - office/administration, No. 5 - photo processing, and No. 8 - vehicle wash rack. In addition, the BTS's supplying water to each of these activities are listed adjacent to the activity.
- . Activities that receive water from BTS 3 are listed under the "OUT" heading: No. 8 - vehicle wash rack, No. 7 - general irrigation, and No. 9 - office/administration irrigation.
- . The table also marks all recycle loops as designated by the word "RECYCLE" next to the vehicle wash rack under BTS 3.

Table 9 summarizes all flow information for each BTS in the network. As shown, the following flow data is provided:

- . Hourly and cumulative flows into and out of the BTS

- . Modified flows into or out of the BTS due to the effects of storage or make-up
- . Minimum storage capacity and required capacity to provide a safety factor
- . Required hourly make-up water if necessary
- . Graphs of the above

In the example shown here, no storage was required, but make-up was needed as can be seen by the hourly flows under the last column.

Table 10 delineates source water usage on an hourly basis for a typical day. The "SUMMARY" section on the left side of the table gives a comparison of water usage for a once-through network with no reuse versus the cascade network and displays the water saved by reuse. On the right side of the table, hourly water drawn from each source is listed.

Table 11 supplies the same information as Table 9 for final effluent discharged from the base. Again, a comparison is made between a once-through and the cascade system.

Table 12 summarizes the following for each BTS in a network:

- . Removal percentages specified by base personnel. As previously discussed, removals may be specified either by designating a treatment chain to be used at a BTS, or individual-constituent removals.
- . Actual removals used at the BTS to meet all tolerable requirements. If removals are specified in the first column, the program will compare these percentages with those calculated as necessary and place the higher one in column two in each case.
- . The most-stringent tolerable concentration required in the BTS effluent for each constituent.

This table is valuable in that it shows in concise form the degree of treatment necessary at each BTS. From this table, base personnel can isolate those constituents forcing higher levels of treatment and investigate activity pretreatment options to reduce a critical contaminant and perhaps lower the level of BTS treatment.

Table 13 shows an hourly summary of the concentration of each constituent as it enters the BTS, as it exits BTS treatment, and as it is finally discharged from BTS storage. In this way, the hourly fluctuations and effects of peak loads on required treatment can more easily be evaluated.

Table 14 summarizes piping specifications and costs for the cascade reuse system. For each activity, the size, length, and cost of each pipe into and out of the activity is shown. In addition, similar data for make-up to and overflow from BTS's is listed.

Table 15 summarizes size and cost of all required storage facilities and pumps. Storage tank size includes the safety factor discussed in Section III of the main report.

Table 16 summarizes special pretreatment costs at activities and regular treatment chain costs at BTS's. As shown in the example, no activity pretreatment was specified and the program selected the carbon adsorption chain for BTS 3 and the secondary treatment chain for BTS 4 as being the least expensive treatment to meet all requirements. Costs are summarized on both a total capital and yearly O & M basis.

Table 17 summarizes costs for procurement and treatment of source water for each major source on the base, and also the costs associated with each final discharge from the base (excluding treatment).

Table 18 shows the major total system cost summary. Firstly, capital costs for piping, pumping, storage, regular treatment, and special pretreatment are listed and totaled. These capital costs are then translated into annual costs by applying the capital recovery factor that utilizes the cost information supplied by base personnel on interest rates and equipment life. Annual capital and O & M costs are added to source water and discharge costs previously summarized to provide a total yearly cost for the entire cascade network. This cost can be used to compare the benefits and cost effectiveness of different cascade networks.

As can be seen in the example provided, another heading labeled "EXISTING FACILITIES COST" is also provided. In the case where portions of the cascade network are already existing (i.e., source water pumps, secondary sewage treatment plants, etc.), the costs for facilities can be listed and subtracted from the cost summary to obtain the "NET COST" for the cascade reuse system. Many bases

have some type of central wastewater treatment. In the case where the program calls for a more advanced treatment chain than that existing, only the cost of upgrading should be assigned to the reuse system and listed under "NET COST."

## SECTION IV

### BLANK DATA DECKS

This section includes a copy of each of the engineering forms that will be needed and also an entire blank computer form booklet, that contains at least one of every page needed.

It is extremely unlikely that all pages and lines of the computer form deck will be used. The data booklet is provided to accept the maximum amount of data that the program can handle. A typical network will use roughly one-third to one-half of the available deck provided here.

FORM IX

SPECIAL TREATMENT CHAIN COSTS

Treatment Chain Name	No. of Components* in Chain	Cost Coefficients					
		Capital			O&M		
		A	B	C	A	B	C

- \* Be sure to include cost coefficients for each element of the treatment chain. For example, if two pretreatment units are combined in one chain, each must have its cost coefficient listed.
- \* All cost coefficients must be represented in January 1975 \$.

## REGULAR TREATMENT CHAIN COSTS

\* Be sure to include cost coefficients for each element of the treatment chains. For example, if three units are combined in one chain (i.e., secondary, filtration, and carbon adsorption), each must have its cost coefficient listed.

\* All cost coefficients must be represented in January 1975 \$.

TOLERABLE CONTAMINANT LEVELS  
(mg/l)

Handwritten musical notation on a page with 13 staves. The notation consists of a series of vertical lines with horizontal strokes, resembling a form of shorthand or a specific musical notation system. The lines are evenly spaced and run horizontally across the page. The notation is written in a consistent, rhythmic pattern, suggesting a single melodic line or a specific rhythmic exercise. The page is numbered '1' in the bottom right corner.

CAP. FIXED

A vertical ruler scale with markings from 0 to 10 cm. The scale is oriented vertically, with 0 at the top and 10 at the bottom. Major markings are labeled every centimeter (0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10). Minor markings are present every millimeter. The ruler is used to measure the height of the plant in centimeters.

A vertical ruler with markings from 0 to 10 cm. The markings are in millimeters, with major ticks every centimeter and minor ticks every millimeter. The ruler is oriented vertically, with the 0 mark at the top and the 10 cm mark at the bottom.

This image shows a blank sheet of handwriting practice paper. It features five horizontal rows, each designed for practicing letter formation. Each row consists of three parallel lines: two solid outer lines defining the height of capital letters, and a dashed middle line indicating the height of lowercase letters. The rows are evenly spaced across the page, providing ample room for repeated writing exercises.
